

EE 122: Introduction to Control Systems

Problem Set #5: PID control

Name: _____

Submission Date: _____

Problem 1 For the thermostat system from Problem Set 4, implement a PID controller and answer the following questions using your code:

(a) [5 points] Draw a block diagram showing all three components of the PID controller (proportional, integral, and derivative) and how they connect to form the controller, which then connects to the plant (the system being controlled). Label all signals and components clearly.

(b) [20 points] Write down the transfer function of the PID controller and the closed-loop transfer function of the system with the PID controller.

Follow the following experimental setup for the next part:

You are fiddling with the desired temperature in the room to test how quick the thermostat responds. To simulate this behavior, create an array of desired temperatures that each last for 10 minutes and then change to the next desired temperature. For example, you could start with 20°C for 10 minutes, then change to 25°C for the next 10 minutes, and so on. For a total of 60 minutes, simulate the system with the PID controller and plot the actual temperature of the room over time. Assume that the initial temperature of the room is 18°C and that the ambient temperature remains constant at 15°C throughout the simulation.

(c) [75 points] Fill out the following table using your computational experiments with the PID controller. You must compute the rise time, the steady state error, and the overshoot (if any) using your code. In the comments column, explain how each of the three PID parameters (K_p , K_i , and K_d) affects the response. Try at least 5 different combinations of K_p , K_i , and K_d to fill out the table.

#	K_p	K_i	K_d	e_{ss}	Rise Time	Overshoot	Comments on each effect
1							K_p : K_i : K_d :
2							K_p : K_i : K_d :
3							K_p : K_i : K_d :
4							K_p : K_i : K_d :
5							K_p : K_i : K_d :
